ABSTRACT

Vaccines against COVID-19 (and its emerging variants) are an essential global intervention to control the current pandemic situation. Vaccines often cause adverse events; however, the vast majority of adverse events following immunization (AEFI) are a consequence of the vaccine stimulating a protective immune response, and not allergic in etiology. Anaphylaxis as an AEFI is uncommon, occurring at a rate of less than 1 per million doses for most vaccines. However, within the first days of initiating mass vaccination with the Pfizer-BioNTech COVID-19 vaccine BNT162b2, there were reports of anaphylaxis from the United Kingdom and United States. More recent data imply an incidence of anaphylaxis closer to 1:200,000 doses with respect to the Pfizer-BioNTech vaccine.

In this position paper, we discuss the background to reactions to the current COVID-19 vaccines and relevant steps to mitigate against the risk of anaphylaxis as an AEFI. We propose a global surveillance strategy led by allergists in order to understand the potential risk and generate data to inform evidence-based guidance, and thus provide reassurance to public health bodies and members of the public.

Keywords: Adverse event following immunization, Anaphylaxis, COVID-19, Polyethylene glycol, Vaccine

INTRODUCTION

Vaccines against COVID-19 (and its emerging variants) are an essential global intervention to

control the current pandemic situation. Vaccines often cause adverse events; however, the vast majority of adverse events following immunization (AEFI) are due to the protective immune response induced by the vaccine, and not due to an allergic reaction.

Anaphylaxis as an AEFI is uncommon, occurring at a rate of less than 1 per million doses for most vaccines.¹⁻⁵ However, within the first days of initiating mass vaccination with the Pfizer-BioNTech COVID-19 vaccine BNT162b2, there were reports of 2 and 6 anaphylaxis events in the United Kingdom and United States,

Received 7 January 2021; Received in revised form ; Accepted 26 January 2021

Vaccine & manufacturer	Legal status (as of Jan 2021)	Vaccine type	Excipients	Hypersensitivity data to date
CoronaVac (Sinovac, China)	EUA for use in China (essential workers and high-risk groups), Turkey Pending: Indonesia	Inactivated vaccine (formalin with alum adjuvant)	Aluminum hydroxide, disodium hydrogen phosphate, sodium dihydrogen phosphate, sodium chloride	No anaphylaxis events reported during Phase 3 trials (33,620 participants)
Convidicea Ad5-nCoV (CanSino Biologics, Beijing Inst. Biotech., NPO Petrovax)	EUA in China (limited to military use only) Pending: Mexico	Recombinant adenovirus type 5 vector against spike RBD protein	N/A	No anaphylaxis events reported during Phase 3 trials (40,000 participants)
BBIBP-CorV (Sinopharm, Beijing Institute & Wuhan Inst. of Biological Products)	Full authorization for use in China, EUA in Bahrain, Egypt, UAE.	Inactivated SARS-CoV-2 (vero cells) + aluminum hydroxide adjuvant	Aluminum hydroxide, disodium hydrogen phosphate, sodium dihydrogen phosphate, sodium chloride, sodium hydroxide, sodium bicarbonate, M199	No anaphylaxis events reported during Phase 3 trials (48,000 participants)
Pfizer-BioNTech BNT162b2	EUA in Argentina, Bahrain, Canada, Chile, Costa Rica, Ecuador, EU, Israel, Jordan, Kuwait, Mexico, Oman, Panama, Saudi Arabia, Singapore, Switzerland, UK, USA, WHO. Pending: Australia, India, Japan	mRNA-based vaccine (encoding the viral spike (S) glycoprotein)	(4-hydroxybutyl) azanediyl]bis (hexane-6,1-diyl)bis(2-hexyldecanoate)] (ALC-0315), 2-[(polyethylene glycol)-2000]-N,N-ditetradecylacetamide (ALC-0159), 1,2-Distearoyl-sn-glycero-3-phosphocholine cholesterol, potassium chloride, potassium dihydrogen phosphate, sodium chloride, disodium hydrogen phosphate dihydrate, sucrose, water for injection	No anaphylaxis events attributed to vaccine reported in clinical trials (~22,000 participants randomized to active dosing). Approx. incidence of anaphylaxis 1:100,000 with routine use
Moderna mRNA-1273	EUA in Canada, EU, Israel, Switzerland, UK, USA	mRNA-based vaccine (encoding the pre-fusion stabilized spike (S) glycoprotein)	Lipids (SM-102, 1,2-dimyristoyl-rac-glycero-3-methoxy polyethylene glycol -2000 [PEG2000-DMG], cholesterol, and 1,2-distearoyl-snglycero-3-phosphocholine [DSPC]), tromethamine, tromethamine hydrochloride, acetic acid, sodium acetate, and sucrose.	No acute anaphylaxis reactions reported in clinical trials (~15,000 participants randomized to active dosing)

(continued)

Vaccine & manufacturer	Legal status (as of Jan 2021)	Vaccine type	Excipients	Hypersensitivity data to date
ChAdOx1 (Oxford/AstraZeneca; Covishield in India)	EUA in Argentina, Dominican Republic, El Salvador, EU, India, Mexico, Morocco, UK. Pending: Australia, Canada	Replication-deficient viral vector vaccine (adenovirus from chimpanzees)	L-Histidine, L-Histidine hydrochloride monohydrate, Magnesium chloride hexahydrate, polysorbate 80 , Ethanol, Sucrose, Sodium chloride, Disodium edetate dihydrate, Water for injection	No anaphylaxis events reported in clinical trials (~12,000 participants randomized to active dosing)
Covaxin (BBV152) (Bharat Biotech, India)	EUA in India	Inactivated vaccine	N/A	No events report in Phase 1 studies (n = 300)
Sputnik V (Gamaleya Research Inst)	Russia, Palestine	Non-replicating, two-component vector (adenovirus) against spike (S) glycoprotein	Tris (hydroxymethyl) aminomethane, sodium chloride, sucrose, magnesium chloride hexahydrate, Sodium EDTA, polysorbate 80 , ethanol, water for injection	No events report in Phase 1/2 studies (n = 76)
EpiVacCorona (Federal Budgetary Research Institution State Research Ctr, Russia)	Regulatory approval granted in Russia on basis of Phase 1/2 studies	Peptide vaccine with alum adjuvant	Aluminum hydroxide, potassium dihydrogen phosphate, potassium chloride, sodium hydrogen phosphate dodecahydrate, sodium chloride, water for injection	Unknown

Table 1. (Continued) Vaccines against SARS-Cov-2 that are currently approved as of 18 January 2021. EUA, emergency use authorization

respectively.^{6,7} Further surveillance data reported for the United States suggest a rate closer to 1:200,000 doses for the Pfizer-BioNTech vaccine and 1:360,000 for the Moderna vaccine.⁸ The vaccines against COVID-19 are new and some (for example, the mRNA vaccines) have a novel mechanism of action; thus the risk of allergic reactions may be greater than for conventional vaccines. Moreover, it is not surprising that anaphylaxis has not been reported in the clinical trials to-date, given the very low incidence and the exclusion of individuals with a history of hypersensitivity reactions in most studies.

In this paper, we discuss the background to reactions to the current COVID-19 vaccines and relevant steps to mitigate against the risk of anaphylaxis as an AEFI. We propose a global

surveillance strategy led by allergists in order to understand the potential risk and generate data to inform evidence-based guidance.

POTENTIAL CAUSES OF ALLERGIC REACTIONS TO COVID-19 VACCINES

Allergic reactions to vaccines are generally due to adjuvants and other excipients/components in the vaccine such as preservatives and antibiotics, rather than to the active ingredient itself. Vaccines may also contain small amounts of protein present due to the production process (eg, embryonic cells).³

In the United Kingdom, there was an initial concern that patients with atopic disease might be more at risk of allergic reactions. This is because

the 2 recipients in the United Kingdom who were reported to experience anaphylaxis had a history of epinephrine auto-injector carriage due to prior anaphylaxis. The UK regulator issued an advisory statement which listed prior anaphylaxis to a vaccine, medicine or food as a contra-indication.⁷ The US Food and Drug Administration (FDA) did not make the same stipulation, nor did the US Centers for Disease Control and Prevention (CDC), although both the UK regulator and CDC recommended that all vaccine recipients (regardless of atopic history) should be observed for 15 minutes following vaccination, and that facilities (and trained staff) must be available in all vaccination centers.⁹ However, subsequent surveillance data provided further reassurance and the UK regulator lifted the contra-indication 3 weeks later.¹⁰

Polyethylene glycols

The Pfizer-BioNTech vaccine contains 2 novel lipid nanoparticles, 1 of which is “pegylated” (Polyethylene glycol, molecular weight 2000 Da, abbreviated to PEG2000). The Moderna mRNA vaccine also includes a different pegylated lipid (also a PEG2000) (Table 1). Polyethylene glycols, also known as macrogols, are a group of polyether compounds which are widely used in medicinal, cosmetic and household products (including creams and lotions, shampoo, hair

dye, and dental hygiene products). They are formed via the polymerization of ethylene oxide, resulting in PEG polymers of variable chain length and thus molecular weight (Fig. 1).¹¹ PEGs are also used as food additives, as well as in a variety of industrial processes.¹² With respect to the COVID-19 vaccines, the inclusion of a pegylated nanoparticle encapsulating the mRNA impairs enzymatic degradation of the mRNA, increases its water-solubility, and thus bioavailability of the lipid nanoparticle.

PEGs were previously considered to be biologically inert, a feature which has contributed to their widespread use. They form the active ingredient in laxatives and bowel preparations, and are also used as pill binders, in the surface coatings of tablets and as a stabilizer in liquids for injection, lubricant and ultrasound gels, ointments, suppositories, depot injections, bone cements, and organ preservatives.¹¹ PEGylated drugs are becoming more common as they prolong the circulation time of systemic drugs, by impeding metabolism or shielding the drug from immune-degradation. However, there are an increasing number of case reports of immediate-type allergy to PEGs in the literature.^{11,13,14}

PEG allergy is very uncommon, despite its widespread use in household products, medicines, and even foods. The majority of reported

Fig. 1 Polymerization and molecular structure of polyethylene glycol (PEG) and PEG derivatives. Two chemical moieties are common to both PEGs and the PEG derivatives poloxamer and polysorbate; thus cross-reactivity is, in theory, possible. Reproduced from 11 with permission

reactions to PEG in the literature are due to high molecular weight PEGs,¹¹ whereas the lower-molecular weight PEGs found in many household products seem to be less common as a cause of allergic hypersensitivity reactions. The PEG-induced reactions reported in the literature appear to be at the more severe end of the spectrum, with most cases describing multiple episodes of anaphylaxis, often requiring multiple doses of epinephrine.¹¹ Skin testing for the investigation of PEG allergy has also been reported to induce anaphylaxis.¹³

The mechanism(s) which underly PEG allergy are unclear. IgE antibodies to PEG have been detected in some patients with a history of PEG-induced anaphylaxis.¹⁵ PEGs have also been shown to induce complement activation, at least *in vitro*,¹⁶ and may result in complement activation-related pseudo-allergy (CARPA). However, human data relating to complement activation as a mechanism for acute allergic reactions to PEG are inconclusive.^{11,17}

The hitherto very low prevalence of PEG allergy would seem inconsistent with the number of initial cases of anaphylaxis reported to the Pfizer-BioNTech vaccine. This raises the possibility that other triggers, aside from PEG, might be contributory. mRNA-based vaccines are novel vaccines which have not been in widespread use before, so it is important to keep an open mind as to potential triggers for the reported reactions. For example, it is possible that the double stranded RNA within the vaccine is itself immunogenic. Although PEG-sensitization has not been evaluated in healthcare workers, it is possible that healthcare workers may have a higher rate of PEG-sensitization compared to the general population, thus the prioritization of healthcare workers for vaccination might have contributed to the higher-than-expected rate of anaphylaxis to the Pfizer-BioNTech vaccine.

Polysorbate 80 and PEG

Some of the current non-mRNA-based COVID vaccines contain polysorbate 80. However, in contrast to PEG, polysorbate 80 is an excipient in many existing vaccines (eg, DTaP and its analogues, HepB, HPV, pneumococcal conjugate

vaccine, influenza vaccines, zoster) and many medicines; it is also in widespread use as an emulsifier in foods (E433). At least 70% of injectable biological agents and monoclonal antibody treatments contain polysorbates, usually polysorbate 80.¹⁷

Polysorbates are derived from PEGs, but tend to be of lower molecular weights (eg, polysorbate 80 has a molecular weight of 1310 Da), and thus may be much less likely to trigger an allergic reaction. Polysorbates have been reported to induce anaphylaxis-like reactions in animal models (typically via an IgE-independent pathway),¹⁸ but there are very few cases of clinical reactivity in humans in the literature.¹⁸⁻²⁰ This is very surprising, given the widespread use of polysorbates in many pharmaceuticals and in particular, vaccines. IgE-sensitization (without clinical reactivity) is considered to be more common.^{11,13,14} This may also explain why patients with PEG-allergy tend to tolerate polysorbates in food.¹¹ Whether patients with allergy to polysorbates react to higher molecular weight PEGs is unclear. The CDC currently advises against administering either the Pfizer-BioNTech or AstraZeneca vaccines in individuals with allergy to polysorbates.⁹

There are 2 reported cases in the literature of patients with immediate-type allergy to PEG who had cross-reactivity to polysorbate 80 at skin testing.¹⁹ However, in our experience, most patients with PEG allergy tolerate polysorbate 80, including in vaccines. Of note, the AstraZeneca ChAdOx1 vaccine contains polysorbate 80 at a concentration of <100 µg per dose. This is equivalent to the amount of polysorbate 80 found in most injected influenza vaccines, and less than half the amount in influenza vaccines targeted to those over age 65 (eg, Flud).¹⁷ Given the very widespread use of these vaccines on an annual basis, it is reassuring to note that influenza vaccines have not associated with a higher rate of hypersensitivity reactions (akin to that observed for the PEGylated Pfizer-BioNTech COVID-19 vaccine). This is the basis for current guidance from Public Health England in the United Kingdom, that individuals with PEG allergy can receive the AstraZeneca ChAdOx1 vaccine,²¹ although it would seem prudent to keep these patients for at least 30 min observation post vaccination.

RELEVANCE OF ALLERGY IN PATIENT SELECTION FOR VACCINATION

Healthcare workers must follow local authorizations and policy in terms of indications and contraindications for vaccines against COVID-19. The schema in [Table 2](#) provides an outline for precautions which may be prudent dependent on patient history. The anaphylaxis reactions reported to date almost always occurred within 15–30 min of vaccination. There is little information on the risk of vaccine-associated reactions in patients with mast cell disease (such as mastocytosis) nor those who meet published criteria for mast cell activation syndrome (MCAS);²² in the absence of any data, we recommend that such patients can be vaccinated, but may benefit from extended observation of at least 30 min.²³

MANAGEMENT OF ANAPHYLAXIS

The anaphylaxis episodes to the Pfizer-BioNTech vaccine reported to date have

responded to treatment with epinephrine (adrenaline), administered according to International guidelines.²⁴ Note, however, that at least for the cases reported in the United Kingdom, more than 1 dose of epinephrine was required. Staff in all vaccination settings should be trained in the management of anaphylaxis, and have the necessary equipment available. Further guidance relating to the management of anaphylaxis in the vaccination setting can be found in [Appendix A](#) to this article.

A blood sample for evaluation of mast cell tryptase is often of critical importance for accurate diagnosis of vaccine-associated anaphylaxis, particularly in adults, as the history and even symptomology can be ambiguous. The blood sample should be taken 0.5–2 h after a reaction,²⁴ along with a further convalescent/baseline sample (taken at least 24 h after complete resolution of symptoms).

In the context of treating an acute episode of anaphylaxis to a PEG-containing vaccine, it is worth noting that some medicines (such as oral

	Proceed with vaccination	Special precautions	Vaccination contra-indicated
PATIENT CHARACTERISTICS	<ul style="list-style-type: none"> • Prior history of allergic reaction to an identified food or venom or defined group of medication • Inhalant allergy • Family history of allergies • Local (non-systemic) reaction to prior vaccination • Hypersensitivity to non-steroidal anti-inflammatory drugs e.g. aspirin, ibuprofen • Allergen immunotherapy • Patients with stable asthma on biologics 	<ul style="list-style-type: none"> • History of immediate allergic reactions (usually anaphylaxis) to multiple, different drug classes, with the trigger unidentified (this may indicate PEG allergy) • History of anaphylaxis to a vaccine or a parenteral monoclonal antibody preparation • History of idiopathic anaphylaxis • Mast cell disease e.g. systemic mastocytosis 	<ul style="list-style-type: none"> • Prior allergic reaction to the vaccine in question • For an mRNA-based COVID-19 vaccine, prior allergic reaction to another mRNA vaccine • Prior allergic reaction to a component of the vaccine, including PEG (see Table 1)
ACTIONS	<ul style="list-style-type: none"> • Proceed with vaccination as normal, according to local guidelines • An observation period of 15–30 minutes may be advisable. 	<ul style="list-style-type: none"> • Assess risk of possible PEG-allergy • Consider referral to allergist-immunologist • Consider observation for 30 minutes if vaccination proceeds • There are no data to inform recommendations regarding pretreatment e.g. with antihistamine.²² • Pretreatment with antihistamines may mask initial symptoms of a reaction. 	<ul style="list-style-type: none"> • Do not vaccinate with the vaccine in question. • Ideally choose a different COVID-19 vaccine if available and not contra-indicated • Consider referral to allergist-immunologist

Table 2. Schema for contra-indications and precautions when considering vaccination for COVID-19. Adapted from 9

antihistamines) contain PEG.¹³ In general, liquid antihistamines tend not to contain PEG, but clinicians are advised to check their local formulary for specific information.

CHOICE OF VACCINE AFTER ANAPHYLAXIS TO A FIRST VACCINE DOSE

Individuals who develop a systemic allergic reaction to a vaccine should not receive a second dose of that vaccine, nor a vaccine with similar excipients. For example, patients who react with systemic symptoms of the Pfizer BioNTech vaccine should not be given a second dose of this vaccine, nor should they receive a dose of the Moderna vaccine which is also a mRNA-based vaccine which contains PEG. Although data are not currently available as to protection offered using a combination of different vaccines, current UK advice is that the AstraZeneca vaccine can be used as an alternative (if not otherwise contraindicated, for example, in a patient with a proven allergy to polysorbate 80).²¹

Advice from the British Society for Allergy and Clinical Immunology (BSACI) (and published by Public Health England) advises that individuals who develop just a localized urticarial skin reaction (without systemic symptoms) to the first dose of a COVID-19 vaccine should receive the second dose using the same vaccine, in a setting with full resuscitation facilities (eg, a hospital); a 30 min observation period is advised.²¹

DIAGNOSTIC TESTING

Various algorithms have been proposed for the investigation of vaccine allergy and PEG-associated anaphylaxis.^{13,17} "The investigation of potential PEG-allergy is complicated, and skin testing (both skin prick testing and intradermal testing) has been associated with systemic reactions, including anaphylaxis;^{13,17,25} evaluation should therefore only be performed by those with the relevant expertise and in the appropriate setting. We advise clinicians to consider obtaining venous access prior to skin testing with PEGs, in patients with a history of possible anaphylaxis to PEG. Whilst the concentration of PEG-2000 in the Pfizer-BioNTech vaccine is very small, it is sufficient to elicit a positive intradermal

response in PEG-allergic patients. However, the vaccine is also able to elicit a delayed intradermal response in vaccinated individuals without PEG allergy (S Farooque & P Turner, personal communication).

SURVEILLANCE

The speed and necessity with which vaccines against COVID-19 are being rolled-out requires additional surveillance in order for the community to be able to provide reassurance to the vast majority of individuals and identify potential risk factors for those very few who do experience allergic reactions to the vaccines. This is particularly important in the current climate of vaccine hesitancy. Furthermore, there is a concern as to whether the first dose of vaccine might cause IgE-sensitization, and thus increase the risk of anaphylaxis to a subsequent booster dose of vaccine. In addition, the second dose of the Pfizer vaccine causes a higher rate of AEFI;²⁶ this is not uncommon for non-live vaccines, and is generally thought to be due to a priming effect of the first dose. Whether this impacts on the risk of allergic reactions to the new COVID-19 vaccines is unclear.

Whilst many countries have their own surveillance system, the incidence of anaphylaxis to vaccines is so small that we propose a global strategy. Therefore, World Allergy Organization (WAO) in conjunction with Imperial College London and the Network for Online Registration of Anaphylaxis (NORA) have established a system for healthcare professionals to register potential cases of anaphylaxis and allergic reactions to the different COVID-19 vaccines. We encourage our colleagues around the world to provide de-identified information which will then be assessed against the validated criteria published by the Brighton Collaboration with respect to Anaphylaxis as an AEFI,²⁷ as summarized in [Appendix B](#). These data will allow us, as a community, to monitor the occurrence of allergic reactions to the different COVID-19 vaccines in use. We intend to make this information public via the WAO and NORA websites.

REPORT CASES OF ALLERGIC REACTIONS TO COVID VACCINES AT: [Bit.ly/wao-covid](https://bit.ly/wao-covid).

SUMMARY

In the current climate where widespread uptake of vaccines against COVID-19 is a key global intervention to control the pandemic, it is essential that vaccination proceeds safely and with as few barriers as possible. Both the public and health-care workers need reassurance that the vaccines are safe. We hope guidance such as this document, and the collection of anonymized patient data relating to possible allergic reactions to the vaccines, will play a constructive role in achieving this aim.
